# The Diamonds dataset

- ▶ This large dataset has 53940 rows (diamonds) of ten variables (approx 540,000 values)
- ▶ Slow to process!
- ▶ There are seven numeric variables and three categorical variables
- ▶ We selected diamonds because it was conceptually simple to understand what each variable was measuring, and to have the opportunity to use the analytical techniques taught in STAT394 with a large dataset

# The Variables

red font = categorical variable

- ▶ carat: the diamond's weight
- ▶ cut: a measure of quality (4 levels)
- ▶ color: a measure of colour quality (7 levels)
- ▶ clarity: a measure of clearness (6 levels)
- ▶ x: length in mm
- ▶ y: width in mm
- ▶ z: depth in mm
- ▶ depth: total depth percentage
- ▶ table: width of top of diamond relative to widest point
- ▶ price: the price of the diamond in US dollars

# Leading Question 1

- ▶ How can we best predict diamond price using the other variables?
- ▶ We intend to use the following techniques to investigate this question:
- ▶ Stepwise Regression, Principal Components Analysis, Principal Components Regression

# Multiple Regression

- ▶ Starting with the full model we used a stepwise regression procedure to find the best model for predicting diamond price.
- ▶ According to AIC the best model was:
- ▶  $\text{price} \sim \text{carat} + \text{cut} + \text{color} + \text{clarity} + \text{depth} + \text{table} + x$
- ▶ All variables excluding y and z are significant in the model
- ▶ The 'best' model had an Adjusted  $R^2$  of 91.98%

# Regression Assumptions

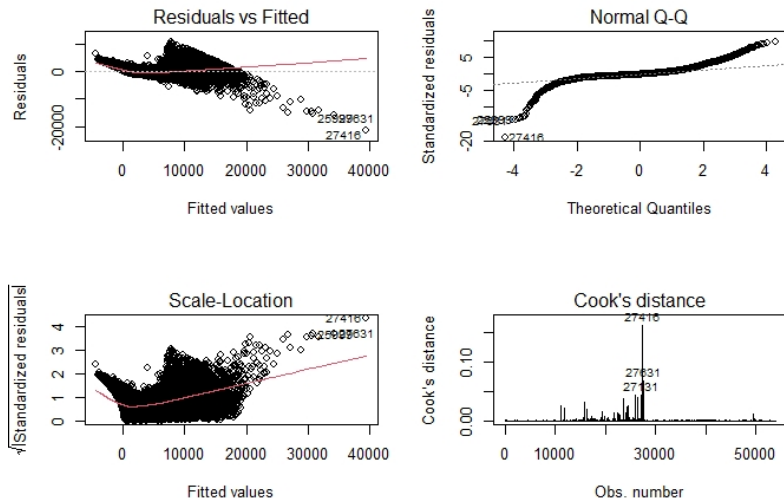

Figure 5: Regression Diagnostics

# Principal Components Analysis: Screeplot

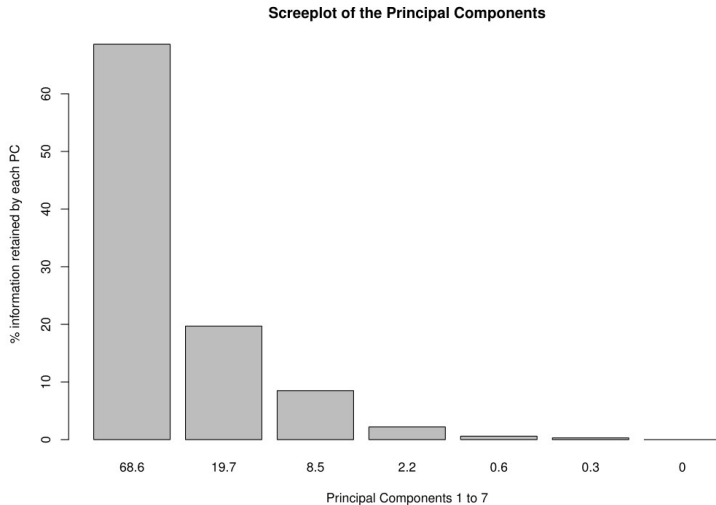

Figure 6: PCA Screeplot

# Principal Components Analysis: Eigenvectors

Figure 7: Plot of EigenVectors

## Biplot

Figure 8: PCA Biplot

# Principal Components Regression

- ▶ We conducted a Principal Components Regression with diamond price as the response variable
- ▶ The PCA excluding price was almost identical to the original PCA
- ▶ We were able to explain over 80% of the variation in price using just the first two principal components as predictors
- ▶ A more parsimonious model!

## Summary of Models Predicting Diamond Price

Model	No. of Predictors	Adjusted $R^2$
Full Model	9	0.9198
Best Model	7	0.9198
Two PC	2	0.8092
All PC	6	0.8695

## Problems encountered

- ▶ Multiple regression: didn't work well without the categorical variables
- ▶ Despite a correlation of 0.9216, 'carat' (a measure of weight) was not a great predictor of 'price'
- ▶ LDA not able to separate different levels of the categorical variables

## Colour-coded scatterplot

Figure 9: Carat vs Price vs Clarity

## Slicing the dataset vertically

Figure 10: Carat vs Price vs Clarity: vertical slice

## Zoomed in version of vertical slice

Figure 11: Carat vs Price vs Clarity: sliced 1

## Colour bands more evident in sliced version

# Linear Discriminatory Analysis

Figure 13: LDA ordination plots

# Conclusion

- ▶ Achieved the primary aim to find the best predictor for 'price'
- ▶ Best model  $\rightarrow \text{price} \sim \text{carat} + \text{cut} + \text{color} + \text{clarity} + \text{depth} + \text{table} + x$
- ▶ Regression using the PCs produced a reasonable result, even without the categorical variables
- ▶ LDA did not work well due to the amount of overlap between the different levels of the categorical variables - the diamonds dataset presented a tricky classification problem
- ▶ Lots of learning figuring out why things did not work!
- ▶ Thanks for listening!! :):)
